(57) ABSTRACT

A process for removing hydrogen sulfide, other sulfur-containing compounds and/or sulfur and mercury from a gas stream contaminated with mercury, hydrogen sulfide or both. The method comprises the step of selective oxidation of hydrogen sulfide (H2S) in a gas stream containing one or more oxidizable components other than H2S to generate elemental sulfur (S) or a mixture of sulfur and sulfur dioxide (SO2). The sulfur generated in the gas stream reacts with mercury in the gas stream to generate mercuric sulfide and sulfur and mercuric sulfide are removed from the gas stream by co-condensation.

CROSS-REFERENCE TO RELATED APPLICATIONS

This application, which claims the benefit of U.S. Provisional Application 60/427,742, filed Nov. 19, 2002, is a continuation-in-part of pending U.S. application Ser. No. 10/358,404, filed Feb. 3, 2003 which in turn claims the benefit of U.S. Provisional Application 60/367,891, filed Mar. 25, 2002; U.S. Provisional Application 60/388,322, filed Jun. 13, 2002; and U.S. Provisional Application 60/420,694, filed October 22, 2002. Each of these applications is incorporated by reference herein in its entirety.

BACKGROUND OF THE INVENTION

The implementation of stricter emission limits for hydrogen sulfide (H\textsubscript{2}S) and sulfur dioxide (SO\textsubscript{2}) has stimulated the development and improvement of processes for the desulfurization of natural gas, synthesis gas, gasification streams and other gas streams used or generated in petrochemical processing, oil recovery and coal utilization. For example, the level of H\textsubscript{2}S in natural gas must be lowered to 4 ppmv to meet pipeline specifications. Sulfur removal or desulfurization processes can also be applied to offgas generated in digesters or in waste water treatment, or to geothermal gases.

Desulfurization is often required for applications other than natural gas, including purification of gasification streams, associated gas from wells, and various gas streams generated in petroleum refining. Hydrogen and CO are the products of the gasification of coal, hydrocarbons, biomass, solid waste and other feedstocks. Gasification is most generally any process where carbon-containing materials are converted into product gases containing primarily carbon monoxide (CO) and hydrogen (H\textsubscript{2}). Various gasification processes are known and practiced in the art.

The gas products generated by gasification can be used to generate electricity or steam or can be used in chemical synthesis to make methyl alcohol (methanol), higher alcohols, aldehydes, or synthetic fuels (via Fischer-Tropsch catalysis). Because one of the uses of gasifier product gas is to make chemicals, it is frequently referred to as synthesis gas or syngas (Sutterfield, C. N. (1991) Heterogeneous Catalysis in Industrial Practice, 2\textsuperscript{nd} ed., McGraw-Hill). In most gasification processes, sulfur compounds present in the feedstock are converted into hydrogen sulfide, which appears in the product gas. Hydrogen sulfide must be removed from the CO and H\textsubscript{2} mixture before the gas can be used for power generation because burns when it generates sulfur dioxide emissions from the power plant. Hydrogen sulfide must be removed from the CO and H\textsubscript{2} used for chemical synthesis because H\textsubscript{2}S irreversibly damages the catalysts used to make alcohols, aldehydes, and other products.

Mercury can be a significant contaminant in gas streams derived from fossil fuels such as coal (e., by gasification) and in natural gas. Mercury can also be a significant contaminant in flue gas emitted from coal-fired power plants. Mercury is removed from such gas streams to minimize its undesirable environmental release and to minimize the potential detrimental effects that it may have on gas stream processing equipment. The levels of mercury present in any gas stream can vary widely dependent upon the type of gas stream and its origin.

Various methods have been reported in the art for the removal of mercury from gas streams, including injection or spraying of dry sorbents (e.g., activated carbon sorbents) or adsorbents, chemisorption methods (e.g., using chemically promoted sorbents), and scrubbing (e.g., with aqueous carbonate, sulfide or polysulfide solutions). The following U.S. patents or published PCT applications relate generally to removal of mercury from natural gas or synthesis gas (U.S. Pat. Nos. 5,034,203; and 5,053,209; and WHO 94/0503) or to removal of mercury from combustion gases or flue gas (U.S. Pat. Nos. 6,214,304; 5,607,496; and 6,521,021); U.S. Pat. No. 6,580,318 relates to an adsorption powder for removing mercury from high temperature, high moisture gas streams.

Granville, E. J.; Penfield, H. W.; and Hangis, R. A. (April 2000) Industrial Engineering Chem. Res. 39:1020-1029 report the results of screening for sorbents capable of removing elemental mercury from various carrier gases. Sorbents screened included, among others, activated carbons, promoted activated carbons, certain metal oxides dispersed on supports (e.g., vanadium pentoxide and molybdenum oxide dispersed on a magnesium silicate support, manganese oxide or chromium oxide supported on alumina and a ferric oxide sorbent); a platinum sorbent; a thiol promoted aluminosilicate sorbent and a molybdnum sulfide sorbent. The reference also provides a brief overview of sorbent technology. U.S. Pat. No. 6,619,263 relates to methods and systems for removing certain pollutants from gas streams, such as combustion gases which employ sorbents or combinations of sorbents. Mercury is removed by being used in an alumina sorbent. U.S. Pat. No. 5,827,352 relates to use of sorbent and water injection to remove mercury from gas streams.

U.S. Pat. No. 5,904,042 relates to a method to remove elemental mercury from a gas stream by first reacting the gas stream with an oxidizing solution to convert the elemental mercury to soluble mercury compounds and then passing the gas stream through a wet scrubber to remove the mercuric compounds and any oxidized constituents.

U.S. Pat. No. 6,249,217 relates to preventing release of heavy metals, such as mercury, using ultraviolet radiation to oxidize mercury, in exhaust gas, to its ionic forms which are less volatile. U.S. Pat. No. 6,576,972 also relates to removing elemental mercury from gas streams using UV irradiation.

U.S. Pat. No. 4,044,098 relates to a process for removal of mercury from gas streams using hydrogen sulfide and amines. The method is particularly applied to sulfur-free natural gas containing mercury. Hydrogen sulfide is added to the gas stream in excess of the stoichiometric amount needed to precipitate sulfides of mercury. Mercury is reported to precipitate out of the gas and the gas is then contacted with an amine to absorb hydrogen sulfide.

U.S. patent application Ser. No. 10/358,404, filed Feb. 3, 2003 and published as U.S. publication no. 2003 0194366A1 relates to catalysts and catalytic methods for the selective oxidation of hydrogen sulfide in a gas stream to generate elemental sulfur, sulfur dioxide or both. Employing the catalysts and methods therein, hydrogen sulfide can be selectively oxidized in the presence of other oxidizable species (including, aliphatic hydrocarbons, aromatic hydrocarbons, carbon dioxide, hydrogen or carbon monoxide) that may be present in the gas stream. The catalysts and methods therein are particularly applicable to the removal of hydro-
gas sulfide from gas streams, including natural gas, synthesis gas, and other gas streams generated or used in petroleum refining and processing. This application and its published counterpart are each incorporated by reference herein for teachings and descriptions of selective H_{2}S oxidation catalysts, methods for selective oxidation of H_{2}S, catalytic reactors and catalytic reactor systems.

The present invention is based at least in part on the discovery that mercury in gas streams, such as natural gas and synthesis gas, can be removed or its levels significantly reduced by treatment employing certain selective oxidation processes described in U.S. patent no. 2005 0194366A1.

SUMMARY OF THE INVENTION

This invention relates to a process for removal of hydrogen sulfide, sulfur and mercury from gas streams, particularly natural gas streams and synthesis gas streams, containing mercury. Such gas streams typically contain undesired levels of hydrogen sulfide or other sulfur-containing compounds which can be converted to hydrogen sulfide. The process of this invention converts hydrogen sulfide in such gas streams at least in part to elemental sulfur which is condensed and removed from the gas stream. Elemental mercury present in such gas streams in which sulfur is generated is converted to mercuric sulfide in the presence of sulfur and also removed in the sulfur condenser. The process of the invention can be used for gas streams containing one part per billion to one part per million mercury. In an embodiment, the gas stream contains 10-30 ppb mercury. In different embodiments, the process of the invention permits greater than 85%, greater than 90%, greater than 95%, or greater than 99% removal of elemental mercury.

The process of the invention removes both sulfur and mercury in the sulfur condenser. Therefore, the separate mercury removal step typical of other gas treatment processes is eliminated.

In the process of this invention, selective oxidation of hydrogen sulfide (H_{2}S) in a gas stream generates sulfur or a mixture of sulfur and sulfur dioxide. Selective H_{2}S oxidation applied to such gas streams can generate sulfur or a mixture of sulfur and sulfur dioxide without substantial oxidation of the one or more oxidizable components in the gas stream other than H_{2}S and the methods can be used to remove mercury. The methods herein are useful, for example, for the selective oxidation of H_{2}S to sulfur or sulfur and SO_{2} in the presence of hydrocarbons, hydrocarbon oxygenate, sulfated hydrocarbons, aromatic hydrocarbons, aliphatic hydrocarbons, carbon dioxide, hydrogen or carbon monoxide and the removal of sulfur and mercury contaminants. The methods herein are particularly useful for the selective oxidation of H_{2}S and mercury removal in gas streams containing natural gas (substantially methane), in gas streams containing one or more low molecular weight volatile hydrocarbons (methane, ethane, propane, butane, etc.), in gas streams containing one or more natural gas liquids (NGLs, e.g., pentanes (C_{5})-nonanes (C_{9})), in gas streams containing aromatic hydrocarbons, such as benzene, toluene, ethylbenzene and xylene (BTXE) and in gas streams, particularly synthesis gas streams, containing carbon monoxide and hydrogen.

Preferred methods of this invention are those that function in gas streams containing relatively high levels of light hydrocarbons, for example, in gas streams containing 50% or more by volume of methane or in methane rich gas containing 90% volume or more methane, without substantial oxidation of the hydrocarbon. Preferred methods of this invention function for desulfurization of, and mercury removal from, natural gas streams containing low molecular weight hydrocarbons other than methane (ethane, propane, butanes, heptanes, hexanes, etc.) without substantial oxidation of the hydrocarbons. Preferred methods of this invention function for desulfurization and mercury removal in natural gas streams containing aromatic species, such as BTXE without substantial oxidation of the aromatic species.

In specific embodiments, in the methods of this invention a gas stream containing mercury, H_{2}S, and other oxidizable components is contacted with a mixed metal oxide oxidation catalyst at a temperature less than or equal to about 500 °C. In the presence of a selected amount of oxygen to generate sulfur or a mixture of sulfur and SO_{2} wherein less than about 25 mol % by volume of the oxidizable components other than H_{2}S and other sulfur-containing compounds are oxidized by the oxygen. In preferred methods less than about 10 mol % by volume of the oxidizable compounds other than H_{2}S and other sulfur-containing species are oxidized by the oxygen. In more preferred methods less than about 1 mol % by volume of the oxidizable compounds other than H_{2}S and other sulfur-containing species are oxidized by the oxygen.

Gas streams may contain other sulfur-containing species which are either oxidized directly, or are first converted to H_{2}S which is thereafter oxidized to generate sulfur or a combination of sulfur and SO_{2}. Sulfur-containing species that may be present in gas streams include, among others, H_{2}S, SO_{2}, CS_{2}, COS, and mercaptans.

Oxidation selectivity of the methods of this invention is at least in part controlled by use of temperatures less than or equal to about 500 °C. Decreasing the temperature at which the catalytic oxidation of H_{2}S occurs generally minimizes the oxidation of oxidizable components other than H_{2}S and sulfur. The temperature of the reactor should, however, be maintained above the dew point of sulfur, for given process conditions, so that sulfur does not condense onto the catalyst or in the catalytic reactor system. The temperature should also be maintained sufficiently high to obtain good catalyst efficiency (measured as % conversion of H_{2}S present). When condensible levels of sulfur are produced in the process, mercury (it is believed as mercuric sulfide) is removed during condensation of the sulfur.

Good catalyst efficiency means that 50% of more of the H_{2}S is converted to sulfur or a combination of sulfur and SO_{2}. Preferably the catalyst and other conditions are selected to achieve 85% efficiency or more for conversion of H_{2}S into sulfur or a combination of sulfur and SO_{2}. More preferably 95% or more efficiency of conversion of H_{2}S is achieved and most preferably 99% or more efficiency of conversion is achieved. Preferred high efficiency catalysts also exhibit long lifetimes being resistant to catalyst deactivation in the presence of oxidizable species other than H_{2}S, to deactivation by other sulfur containing species or to water vapor. In specific embodiments the catalytic reaction is conducted at temperatures between about 100 °C and about 400 °C. Improved selectivity of oxidation of H_{2}S and at least good efficiency of conversion of H_{2}S can be obtained when the temperature at which the catalytic reaction is conducted is below about 350 °C. The reaction temperature is preferably maintained above about 160 °C for satisfactory catalytic activity. In preferred methods of this invention the catalytic reaction is conducted at temperatures ranging from about 160 °C to about 250 °C. In more preferred methods of this invention the catalytic reaction is conducted at
temperatures ranging from about 170° C. to about 200° C. Under conditions where condensable sulfur is formed, mercury is removed.

The amount of oxygen present during the reaction can be adjusted to affect the efficiency of oxidation of H₂S and the relative amounts of SO₂ and sulfur generated on oxidation of H₂S. In principle, sufficient oxygen may be present in a gas stream to allow a desired level of oxidation of H₂S and the generation of SO₂ and sulfur. Most often, however, oxygen, typically added as air, will be added to the gas stream to adjust the ratio of O₂ to H₂S in the gas stream. The amount of oxygen in the gas stream to be contacted with the catalysts of this invention depends on the amount of H₂S present and generally is adjusted to obtain a selected ratio of O₂ to H₂S. Typically the oxygen is adjusted so that the O₂ to H₂S ratio is within a range from about 0.3 to about 2.

Where partial oxidation products, e.g., higher amounts of sulfur compared to SO₂ are desired, lower ratios of O₂ to H₂S are used (about 0.4 to about 1.0). In a specific embodiment, the ratio of O₂ to H₂S is adjusted to about 0.5 to 1.0 to enhance generation of sulfur and facilitate mercury removal. Where higher amounts of SO₂ are desired, higher ratios of O₂ to H₂S (about 1.0 to 1.75 or greater than about 1.75) can be used.

The invention relates to a catalytic process that can be used to oxidize hydrogen sulfide (H₂S) into elemental sulfur, or a mixture of elemental sulfur and sulfur dioxide (SO₂) gas with the selectivity to each product determined by the amount of oxygen present (more specifically the O₂:H₂S ratio), the temperature selected, and variations in catalyst composition. Mercury removal accompanies sulfur condensation. The process can be used to generate SO₂, and sulfur for any process, but is particularly useful for applications to liquid phase sulfur recovery and to desulfurization processes. The catalyst and process can be used to oxidize H₂S into sulfur, for example, for use upstream of liquid recovery systems, sulfur recovery systems such as the Lurgi-Lindemann desulfurization process, and for feeding into conventional Claus units. In the latter application, the catalytic reactor can preferably be used as a replacement for the Claus furnace in a Split Flow Claus Process. The preferred ratio of H₂S to SO₂ for a Claus process is about 2.1. The catalytic reactor of this invention can provide this ratio. However, the reactor can be operated to provide a range of ratios of H₂S to SO₂ (e.g., about 1:1 to about 3:1) which can be processed in a Claus reactor. The catalyst and process can also be used to oxidize H₂S into sulfur, for example, for use upstream of biological treatment processes such as Shell-Paques process, scavenger processes, and aniline acid gas separation processes.

The methods of this invention can be used to desulfurize and remove mercury from gases containing CO and hydrogen, particularly those gases that are categorized as synthesis gas. The methods of this invention are useful for desulfurization of gas streams containing about 1% by volume or more of CO, H₂, or both, are useful for desulfurization of gas streams containing about 10% by volume or more of CO, H₂, or both, and are useful for desulfurization of gas streams containing about 30% by volume of CO, H₂, or both. Additionally, the methods of this invention are useful for desulfurization of synthesis or gasification gas streams containing from 1% to 10% by volume, 2% to 10% by volume or 2% to 10% by volume or more of CO, H₂, or both. In this application, preferred desulfurization catalysts minimally oxidize (oxidize less than about 5% by volume of and more preferably less than about 2% by volume of) the CO and H₂ components of the gas stream. The methods of this invention can be used to remove or reduce mercury levels in gas streams containing from 1 ppb to 1 ppm mercury.

The methods of this invention will also oxidize H₂S into sulfur, or sulfur and SO₂ (dependent upon the amount of oxygen present) when the H₂S is present in natural gas without any substantial oxidation of any of the hydrocarbons present in the natural gas. Mercury is removed when sulfur is condensed. This permits direct removal of H₂S from natural gas without the use of amine pretreatment. The catalyst will oxidize H₂S into sulfur, or sulfur and SO₂ in the presence of saturated hydrocarbons, as well as, aromatic hydrocarbons, specifically BTEX components.

The methods of this invention can also be used to decrease the levels of mercaptans in gas streams. Hydrogen sulfide oxidation of this invention can be carried out between ambient pressure and about 1000 psig in the presence of hydrocarbons, CO, hydrogen, CO₂, or water vapor. More typically, the operating pressure of the reaction can be up to about 500 psig. The maximum allowable operating pressure is determined by the dew point pressures of elemental sulfur, water and hydrocarbons in the system so as to avoid condensation of these components into the liquid phase. This maximum allowable pressure depends on the composition of the gas entering the process and the temperature at which the catalytic reaction is operated.

The catalytic H₂S oxidation technology of this invention can, in addition to removing mercury contaminant, provide a source of SO₂ for sulfur recovery processes (Claus processes) eliminating the need for either shipping in liquid or compressed SO₂ from an external source, or installing a sulfur burner system upstream of a liquid-phase or conventional Claus sulfur recovery plant. This lowers capital and operating costs of the plant by simplifying the process and decreasing the size of the unit compared to the case where extra SO₂ is added either as gas, liquid or from sulfur burning. The size of the plant unit is reduced because the use of any of the conventional methods of supplying the necessary SO₂ increases the total amount of sulfur (sulfur load) that must be processed. The inventive process is also useful in any process where SO₂ is required and a source of H₂S is available.

The inventive process can also, in addition to mercury removal, be used to reduce the sulfur burden of downstream high-efficiency sulfur recovery processes, such as L-CAT and Sulferox. By controlling the catalyst operating temperature and the amount of O₂ added as air, the composition of the product gas from the inventive process can be adjusted so the recovery of elemental sulfur is high and the concentration of SO₂ is very low. This is done by decreasing the amount of O₂ and operating at relatively low temperatures (just above the sulfur dew point) so that some of the H₂S remains unconverted. This gas stream (now with a lower H₂S concentration) is then processed in the sulfur recovery unit.

The inventive process can also specifically be used to replace the furnace of a Split-Flow Claus unit for processing low concentrations of H₂S. For gases with H₂S concentrations below about 40%, it is difficult to obtain stable combustion, if the entire gas stream is to be burned to obtain the correct H₂S to SO₂ ratio. The conventional solution to this problem has been to bypass up to ½ of the gas and burn all of the H₂S in that stream to SO₂ and to then remix the SO₂ stream with the remaining ½ gas stream contain uncon-
converted H₂S before entering the first catalytic Claus stage. The inventive process can be used to generate the required SO₂ for the Split-Flow Claus process. By controlling the amount of air added to the direct oxidation catalytic reactor of this invention and operating at moderate temperatures (approximately 200°C), H₂S can be converted in the split stream into SO₂ and elemental sulfur.

In another specific embodiment, the catalytic direct oxidation reactions and mercury removal of this invention can be combined upstream of art-known Claus Tail Gas Treatments, such as the SCOT process (particularly for medium-scale sulfur removal) or upstream of art-known scavenging chemicals (particularly for small-scale or medium scale sulfur removal).

In further specific embodiments, the catalytic direct oxidation reactions and mercury removal of this invention can be combined with biological sulfur removal processes such as the Shell-Paquex, the THIOPAQ process or the Thiopea DeSO₃ process. The catalytic process of this invention can, for example, be employed to maximize sulfur production and removal, along with mercury, from a gas stream with residual H₂S, SO₂ or mixtures thereof passed directly or indirectly into appropriate aerobic and/or anaerobic biological reactors (containing selected microorganisms for conversion of sulfide and/or sulfate to elemental sulfur).

In another specific embodiment, the catalytic direct oxidation reactions and mercury removal of this invention can be combined with acid gas recycling to generate gas streams that are appropriate for pipeline specifications. Sulfur remaining in a gas stream after application of the direct oxidation can be separated (e.g., condensed along with mercury) from that gas stream and the treated gas stream is recycled back to the direct oxidation unit. This recycling can be performed continuously or as needed to achieve a desired level of sulfur removal. In general any process that can separate acid gases from the gas stream (e.g., that can separate H₂S and/or SO₂ from the gas stream) can be employed for recycling. More specifically, an amine unit, which captures and separates acid gases can be employed. A variety of amine compounds are known in the art which employ various amine compounds for capture of the acid gases. Any amine unit appropriate for the use with a given gas sourc can be used in combination with the direct oxidation of this invention. Those of ordinary skill in the art can readily select an amine unit or other device or system for separation of H₂S and/or SO₂ appropriate for combination with the direct oxidation of this invention and for use with a given gas source.

In another specific embodiment, the invention provides methods for converting hydrogen sulfide into elemental sulfur or a mixture of sulfur and SO₂ in a feed gas stream containing carbon monoxide (CO), hydrogen (H₂) and hydrogen sulfide, and for removing mercury from that gas stream. The method and catalysts of this invention selectively oxidize hydrogen sulfide in such feed streams preferentially without any substantial oxidation of carbon monoxide or hydrogen. For example, the methods and catalysts of this invention can be used to obtain high efficiency conversion of H₂S and mercury removal with substantially no oxidation of CO and hydrogen (e.g., such that less than about 10% by volume of the CO and hydrogen are oxidized).

The catalysts used in the invention can, for example, be employed in the form of particles, pellets, extrudates (of varying sizes) or the like in fixed bed reactors and/or fluidized bed reactors. Catalyst form and size are selected as is known in the art for a given reactor type and reaction conditions. Catalyst reactors employed in the process of this invention may be provided with internal temperature control and/or heat removal systems, particularly where gas streams having higher concentrations of H₂S (>1-2%) are to be treated. Catalytic oxidation processes of this invention can generally be run with space velocity between about 100 and about 20,000 m³ of gas/m³ of catalyst/hour. Alternatively the space velocity can be between about 500 and about 10,000 m³ of gas/m³ of catalyst/hour or between about 1,000 to about 5,000 m³ of gas/m³ of catalyst/hour. The catalysts of this invention can be employed in any catalytic reactor design known in the art appropriate for the pressure and temperature conditions of the reaction and appropriate for receiving the gas stream (with any added air/oxygen and adopted for recycling of gases if desired) to be treated and the catalysts of this invention. Fixed and fluidized bed reactors can be employed, for example. Any art-known sulfur condenser can be employed. The invention also provides a catalytic reactor system for selectively oxidizing hydrogen sulfide in a gas stream containing hydrogen sulfide to sulfur dioxide, sulfur or mixtures thereof while reducing the concentration of mercury in the gas stream. The system includes a catalytic reactor containing a mixed metal oxide catalyst of this invention and a sulfur condenser for removing sulfur produced in the catalytic reaction. The entering gas stream containing hydrogen sulfide and optionally other sulfur-containing species is mixed with an oxygen-containing gas (e.g., air) and contacted with the catalyst in the catalytic reactor at a selected temperature. Sulfur is removed from the gas stream exiting the reactor by condensation in the condenser to produce a treated gas stream containing lower levels of sulfur-containing species than the entering gas stream. The elemental mercury present in the gas stream reacts with sulfur and forms HgS which is removed in the condenser to produce a gas stream with mercury levels reduced. The catalytic reactor system can further be optionally equipped with a recycling system for directing at least a portion of the gas stream exiting the catalytic reactor back through the catalytic reactor (typically being mixed with the entering gas stream and the oxygen-containing gas for removal of additional H₂S or other sulfur-containing species.

The catalytic reactor system of this invention can optionally be combined with upstream guard beds for removal of other undesirable components, for example, for arsenic removal.

The treated gas may be released from the system if the levels of hydrogen sulfide or other sulfur-containing species are sufficiently low. Alternatively, the treated gas may be recycled or passed to downstream processing, for example, for additional treatment to further decrease the levels of hydrogen sulfide or other sulfur-containing species in the gas stream. The downstream processing can include processing in one or more sulfur-removal or recovery processes known in the art. Exemplary downstream processing include, but are not limited to: treating the exiting gas stream with scavenging chemicals; passing the exiting gas stream into a liquid phase redox sulfur removal system; passing the exiting gas stream into a tail gas treatment system; passing the exiting gas stream into a liquid Claus sulfur removal system; or passing the exiting gas stream into a Claus reactor.

The catalytic reactor can optionally be equipped with a gas stream bypass for directing a portion of the entering gas stream directly to downstream processing. A gas stream bypass can be used, for example, to adjust the ratio of H₂S.
to SO₃ that enters downstream processing. A recycling system can also be combined with downstream processing in which at least a portion of the gas stream exiting downstream processing is recycled through the system used for downstream processing or is recycled back through the catalytic reactor. Most preferably, the treated gas exiting the catalytic reactor system with optional downstream processing contains 4 ppmv or less of H₂S.

The invention is further illustrated by the following detailed description, the drawings and specific examples.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 is a schematic illustration of a catalytic reactor configured for the direct oxidation reaction of a sulfur recovery condenser with a sulfur recovery condenser. The process is illustrated for coking or natural gas treatment and has an optional liquid knock out device. Optional downstream processing or recylcing of the gas stream exiting the reactor is indicated.

FIG. 2 is a schematic illustration of the catalytic reactor of the invention combined with a downstream amine unit (one exemplary downstream process) and configured for gas stream recycling.

FIG. 3 is a schematic illustration of an example process configuration in which a catalytic reactor of this invention is positioned upstream of a liquid phase Claus process. The catalytic reactor is operated to generate a mixture of H₂S and SO₂, preferably with a H₂S and SO₂ of 2:1, for introduction into the liquid Claus reactor. An optional sour gas bypass is illustrated to facilitate adjustment of the H₂S and SO₂ as discussed in the specification.

FIG. 4 is a schematic illustration of an example process configuration in which a catalytic reactor of this invention is positioned upstream of a liquid redox sulfur removal process. The I2-O2 process is exemplified.

FIG. 5 is a schematic illustration of an example process configuration in which a catalytic reactor of this invention is positioned upstream of a biological sulfur removal process (Shell-Paques process is exemplified) in which sulfide is converted to sulfur for removal. The caustic scrubber in which H₂S is converted to sulfide as a part of the Shell-Paques process is not specifically shown.

FIG. 6 is a schematic illustration of an example process configuration in which a catalytic reactor of this invention is positioned upstream of a conventional Claus unit (which may be a multi-stage Claus unit). The configuration illustrated is that of a Split-Flow Claus process in which the catalytic process of this invention replaces a furnace or burner (used in the prior art configuration to generated SO₃). Claus tail gas is illustrated as exiting the process. Art-known CTGT, such as the SCOT process, can be applied to treat the tail gas.

FIG. 7 is a schematic illustration of an example process configuration in which a catalytic reactor of this invention is positioned upstream of a Claus Tail Gas Treatment (CTGT) unit. The unit is exemplified by a SCOT process with recycle.

FIG. 8 illustrates Hg removal efficiency and Hg concentration in the sulfur condenser for high sulfur coal (10,000 ppm H₂S in syngas).

FIG. 9 illustrates Hg removal efficiency and Hg concentration in the sulfur condenser for low sulfur coal (100 ppm H₂S in syngas).

DETAILED DESCRIPTION OF THE INVENTION

The invention is based at least in part on the discovery that mercury in gas streams, such as higher gas stream activity gas, can be removed or its levels reduced by treatment employing certain selective oxidation processes. The process of this invention converts hydrogen sulfide in such gas streams, at least in part, to elemental sulfur which is condensed and removed from the gas stream. Elemental mercury present in such gas streams is converted to mercuric sulfide in the presence of sulfur and removed in the sulfur condenser.

Catalysts suitable for use in selective H₂S oxidation and Hg removal processes herein should exhibit low activity for hydrocarbon oxidation (e.g., paraffinic, olefinic and aromatic hydrocarbons); resist deactivation by common natural gas contaminants (e.g., BITEX); preferably give high conversions for H₂S oxidation (lowering the catalyst bed volume); exhibit high selectivity for SO₂ under selected conditions; and exhibit high selectivity for elemental sulfur under selected conditions.

The catalysts useful for the present invention which have been found to exhibit the listed properties are mixed metal oxides comprising a low oxidation activity metal oxide selected from the group of titania, zirconia, silica, alumina or mixtures thereof in combination with one, two, three, four or more metal oxides having a higher oxidation activity compared to the low oxidation activity metal oxide. Both alumina and silica and alumina are useful as low oxidation activity metal oxides. The higher oxidation activity metal oxides can be transition metal oxides, lanthanide metal oxides or both selected from oxides of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, Mo, Ta, Ru, Rh, Pd, Hf, Ta, W, Re, Os, Ir, Pt, Au, La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, or mixtures thereof. Preferred high oxidation activity transition metal oxides are those that are oxides of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, Mo, W, and mixtures thereof. A preferred high oxidation activity lanthanide metal oxide is that of La. More preferred higher oxidation activity metal oxides are oxides of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, Mo, or mixtures thereof. Yet more preferred higher oxidation activity metal oxides are oxides of Nb, Mo, Cr, Mn, Fe, Co or Cu. Preferred mixed oxide catalysts of this invention comprise two, three or four high oxidation activity metal oxides.

Selected catalysts useful for the invention include mixed metal oxides containing 50% by weight or more of titania, silica, alumina or mixtures thereof (a low oxidation activity metal oxide) in combination with one or more metal oxides of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, or Mo. Selected catalysts useful for the invention include mixed metal oxides containing from about 0.1 to about 10% by weight of one or more metal oxides of Cr, Mn, Fe, Co, Cu, Nb, or Mo wherein the remainder of the catalyst is titania, zirconia, silica, alumina or a mixture thereof. Selected catalysts useful for the invention include mixed metal oxides containing about 0.1% to about 15% by weight of an oxide of Mo and optionally about 0.1% to about 10% by weight of one or more metal oxides of Nb, Fe, Co
or Cu wherein the remainder of the catalyst is titania, zirconia, silica, alumina or a mixture thereof.

Selected catalysts useful for the invention include: those containing from 0.1% to about 10% by weight of an oxide of Mo, an oxide of Nb or both, and from about 1% to about 10% by weight of an oxide of Fe, Cu or Co; those comprising about 1 to about 10% by weight copper oxide; about 1 to about 10% by weight niobium oxide; and about 0.1 to about 1% by weight molybdenum oxide with the remainder being titania or a mixture of titania and silica; those comprising about 1 to about 10% by weight iron oxide; about 1 to about 10% by weight niobium oxide, and about 0.1 to about 1% by weight molybdenum oxide with the remainder being titania or a mixture of titania and silica; and those comprising about 1 to about 10% by weight cobalt oxide; about 1 to about 10% by weight niobium oxide, and about 0.1 to about 1% by weight molybdenum oxide with the remainder being titania or a mixture of titania and silica.

Selected catalysts useful for the invention include mixed metal oxides containing 75% by weight or more of titania, silica, alumina or mixtures thereof (a low oxidation activity metal oxide) in combination with one or more metal oxides of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, or Mo. Selected catalysts useful for the invention include mixed metal oxides containing 75% by weight or more of titania, silica, alumina or mixtures thereof (a low oxidation activity metal oxide mixture) in combination with one or more metal oxides of Cr, Mn, Fe, Co, Cu, Nb, or Mo. Selected catalysts useful for the invention include mixed metal oxides containing about 1% to about 25% by weight of one or more metal oxides of Cr, Mn, Fe, Co, Cu, Nb, or Mo wherein the remainder of the catalyst is titania, zirconia, silica, alumina or a mixture thereof. Selected catalysts useful for the invention include those containing about 1% to about 25% by weight of one or more metal oxides of Mo wherein the remainder of the catalyst is titania, silica, alumina or a mixture thereof. Selected catalysts useful for the invention include mixed metal oxides containing about 1% to about 25% by weight of one or more metal oxides of Mo wherein the remainder of the catalyst is titania, silica, alumina or a mixture thereof. Selected catalysts useful for the invention include those containing about 1% to about 25% by weight of one or more metal oxides of Mo wherein the remainder of the catalyst is titania, silica, alumina or a mixture thereof. Preferred the majority component (more preferably 50% to about 90%) by weight of all selected catalysts is titania.
of the binder is unimportant; however, in the preferred formulation, aluminum oxide is avoided to minimize any sulfation reactions that may occur by reaction of the aluminum oxide with SO₂. The amount of binder can vary from 1 wt % to 25 wt % with the preferred amount being 10% of the original weight of the powder mixture (e.g. 10 g of binder for each 100 gm of mixed powders). Mixed metal oxide catalysts of this invention can comprise up to about 10% by weight of a binder. The preferred binder is silica.

The catalysts used in the invention can be prepared by any method of combination of methods known in the art. However, the catalysts are preferably prepared by co-forming methods or by a combination of co-forming and impregnation techniques as described in the U.S. publication no. 2003/0149366A1. Coprecipitation and combinations of coprecipitation and impregnation or coprecipitation and co-forming and combinations thereof can also be used to prepare the catalysts. Starting materials (various metal compounds) for preparation of the catalysts herein are readily available. As is known in the art, starting materials may contain low levels of impurities, particularly metal impurities, in general such impurities have not been found to affect catalytic activity. Higher purity starting materials may be employed or art-known methods may be employed to purify starting materials in those cases in which a detrimental effect of impurities on activity is detected.

Catalysts useful in this invention include those prepared by calcining a mixed metal oxide powder at a temperature of about 300°C to 550°C and those prepared by calcining a mixed metal oxide powder at a temperature of about 400°C to 450°C.

Technical grade materials (generally containing 95% or more by weight of the chemical of interest) are sufficiently pure for preparing the preferred catalysts. Small levels of impurities of various metals (V, Cr, Mn, Fe, Co, Ni, Cu, Nb, Mo, Te, Ru, Rh, Pd, Hf, Ta, W, Re, Os, Ir, Pt, Au, La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu) present as impurities will not significantly adversely affect catalytic properties.

The catalysts used in the invention are prepared as metal oxides. After exposure to gas streams containing H₂S, SO₂, and/or other sulfur-containing species, the catalysts may be converted at least in part to sulfide or sulfate which are active for oxidation. In addition, the oxidation states of the metal oxides may change during the reaction or pretreatment.

Metal oxide catalysts used in the invention can be characterized by XRD, XPS, XRF and multi-point BET pore size distribution assays, if desired. Pore size and pore-size distribution of the catalysts herein can be adjusted if desired by employing methods that are well-known in the art. For example, the pore size and pore-size distribution of a given catalyst can be increased by the addition of pore-forming precursor materials to the metal oxide powders, such as hydroxyethylcellulose or polyethylene glycol, which will burn away during calcination, leaving behind larger pores.

The surface area of a given catalyst can be measured using methods that are well-known in the art and surface area of a given catalyst can be adjusted or selected using methods that are well-known in the art. Calculation of this invention includes those having a surface area ranging from about 90 to about 150 m²/g.

The methods herein can be used generally in any application where sulfur or a selected combination of SO₂ and sulfur are desired products and the feedstock contains mercury and H₂S. Sulfur dioxide or sulfur may be desired as a starting material or reagent (e.g., SO₂ may be employed as an oxidizing agent) in a process (e.g., in a synthetic process). The methods of the invention can be employed to remove or reduce the level of undesired H₂S and Hg present in a gas stream. In this case, SO₂ and/or sulfur may be more readily removed from a given gas stream than H₂S.

The catalytic processes of this invention are designed to oxidize H₂S, at least in part, to elemental sulfur in a gas stream that contains H₂S concentrations from a few ppm up to tens of percents. The inventive process can generally be used to remove or decrease the levels of H₂S in the gas stream, to generate elemental sulfur for various applications, to generate a selected mixture of SO₂ and sulfur or a selected mixture of H₂S and SO₂.

Again in general, the catalytic oxidation and the removal method of the invention and a catalytic reactor carrying out the oxidation method can be combined upstream or downstream as appropriate with any one or more compatible sulfur recovery or removal processes that are known in the art. The methods herein can in general be combined with any art-known sulfur recovery or removal process that can be operated such that the pressure range, temperature range, and/or component concentration (e.g., H₂S, SO₂, etc.) range, if any, of any gas stream(s) linking the processes are within (or can be reasonably adjusted to be within) the operational range of the invention process.

For example, the inventive process can be operated downstream of a chemical or catalytic process in which various sulfur-containing species in a gas stream are converted to H₂S. More specifically, the H₂S oxidation and Hg reduction methods herein can be combined with known methods (e.g., hydrogenation/hydrosulfurization process) for converting other sulfur containing species, such as SO₂, COS, CS₂, and/or mercaptans (e.g., RSH, R is aliphatic) to H₂S.

The inventive process can be operated downstream of a combustion, adsorption, fractionation or reactive process which decreases the level of any undesired gas component, e.g., H₂S (assuming residual H₂S remains), SO₂, particulates, aerosols (e.g., containing hydrocarbons), condensate (e.g., containing heavier hydrocarbons), heavier hydrocarbons, etc. The inventive process can be operated downstream of a concentration, fractionation, adsorption or reactive process that increases the level of any desired gas component. The inventive process can be operated downstream of a less than completely efficient sulfur removal process for removal of residual H₂S to increase efficiency. Alternatively, or in combination, the inventive process can be operated downstream of a sulfur removal or recovery system that is detrimentally affected by the presence of SO₂ to reduce SO₂ levels entering the system and improving overall efficiency.

Compatible processes can be linked, typically by transfer of a product gas stream from one process to the feed inlet of another process directly or by intervening cooling, heating, pressure adjustment, water removal, solvent removal, filtering equipment or related processing equipment as will be appreciated by those of ordinary skill in the art.

Selective oxidation of H₂S in the presence of other oxidizable components is achieved by use of catalysts herein, in appropriate catalytic reactor systems, and with selection of the temperature at which the catalytic reaction is conducted. In general, any type of catalytic reactor can be
employed that is appropriate for bringing the gas stream to be treated into contact with the catalyst and other reactant (air or oxygen). Fixed bed and fluidized bed reactors can be employed. Typically the feed gas stream is heated sufficiently high before entering the catalytic reactor such that the temperature in the reactor is within a relatively small range around a selected temperature. A catalytic reactor for conducting the H₂S oxidation of this invention can, alternatively or in addition, be provided with a heater or cooling equipment as needed to maintain the desired temperature range. A catalytic reactor for the invention process can optionally include metering valves for controlling gas streams entering and leaving the reactor. Gas flows (e.g., component concentrations), pressures and temperatures in the reactor can be measured and controlled using methods and equipment that is well-known in the art.

The temperature of the reaction is kept below about 400°F. To avoid or minimize unwanted oxidation and to decrease energy requirements. Generally, the more active the metal oxide catalyst, the lower the reaction temperature that should be used with the caveat that the reaction temperature should be maintained sufficiently above the sulfur dew point to avoid detrimental levels of sulfur condensation in the reactor. Sulfur condensation onto the catalyst which can lead to catalyst deactivation and may require catalyst regeneration is preferably avoided. The more preferred temperature range for operation is between about 160°C to about 250°C, dependent upon the sulfur dew point.

Methods of this invention can be used to oxidize H₂S substantially to S (with less than about 10-15 mol % SO₂) or substantially to SO₂ (with less than about 10 mol % S). Methods of this invention can be used to oxidize H₂S essentially to S (with less than about 5 mol % of SO₂) or essentially to SO₂ (with less than about 5 mol % of S).

The catalysts and catalytic process of this invention are selective for the oxidation of H₂S in the presence of various other oxidizable species, including aliphatic and aromatic hydrocarbons, CO and H₂, as well as in the presence of non-oxidizable components such as CO₂.

Because methane, BTEX and NGL (natural gas liquid) hydrocarbons are not oxidized during H₂S oxidation at temperatures below about 300°C, the inventive process can be used to directly desulfurize natural gas streams that contain either low or high concentrations of methane and CO₂ as well as BTEX and NGL hydrocarbons.

A wide range of natural gas compositions can be treated for sulfur removal by the processes of this invention. Table 1 lists a field composition for a low concentration methane gas and Table 2 lists the composition of a methane-rich gas. Either gas can be effectively treated using the inventive direct oxidation process of this invention or employing sulfur removal and recovery processes of this invention in which the direct oxidation process is combined with art-known sulfur recovery or removal systems.

The direct oxidation process of this invention can be employed alone or in combination with other sulfur removal or recovery systems for high-pressure as well as low-pressure gas streams for H₂S removal. Typically low pressure gas streams constitute gas streams at 0-50 psi and high pressure gas streams constitute streams that are available at pressures higher than 50 psi. All of the processes that follow the direct oxidation process can be operated at high pressures, typically up to 1000 psi. In addition to natural gas streams and synthesis gas, the processes herein are also specifically applicable to removal of H₂S from refinery fuel.

The direct oxidation process of this invention can be employed alone or in combination with other sulfur removal or recovery systems for high-pressure as well as low-pressure gas streams for H₂S removal. Typically low pressure gas streams constitute gas streams at 0-50 psi and high pressure gas streams constitute streams that are available at pressures higher than 50 psi. All of the processes that follow the direct oxidation process can be operated at high pressures, typically up to 1000 psi. In addition to natural gas streams and synthesis gas, the processes herein are also specifically applicable to removal of H₂S from refinery fuel.
gas, from gas streams of CO₂, hydrocarbons, and from gases generated during waste water treatment.

Direct Oxidation of H₂S and Hg Removal with optional Sulfur Recycling and Tail Gas Treatment

The methods of this invention can be used in a direct oxidation process to remove sulfur and mercury from a sour natural gas stream. FIG. 1 illustrates an exemplary selective oxidation process and FIG. 2 illustrates a direct oxidation reactor upstream of a standard amine unit which exemplifies downstream processing with a tail gas treatment unit which separates acid gases from the process stream and allows H₂S and/or SO₂ to be cycled back to the direct oxidation unit.

The process is illustrated for application to natural gas of syngas treatment. In the illustrated process, sour gas first enters a knockout drum (402) via inlet (401) where any natural gas liquids are removed. The use of a knockout drum or related device element is optional and dependent upon the components present in the gas stream to be treated. The sour gas (403), the term is used generically herein to refer to gas streams containing H₂S and/or SO₂, is then heated (heater, 425) to a temperature at least above the dew point of sulfur (calculated for 95% conversion of H₂S into elemental sulfur), mixed with air (inlet 413) and passed into the catalytic reactor (415). In certain configurations, the gas is heated to a temperature such that the gas will be at the desired reaction temperature when it reaches the catalytic reactor. In other configurations, the catalytic reactor may be provided with heaters and or temperature control to allow selection of reaction temperature.

An optional guard bed (not shown) may be included upstream of the catalytic reactor (415) to remove undesirable components such as arsenic. Sorbents to remove arsenic and other undesirable components are known to those skilled in the art.

The mixture of air and sour gas enters the catalytic reactor (415) which contains the direct oxidation catalyst. This catalytic reactor can have any design appropriate for the selected reaction conditions and specifically can be either a fixed bed or fluidized bed reactor. The airflow rate is adjusted (flow meter not shown) so that the oxygen to hydrogen sulfide is preferably between about 0.4 and about 5 and more preferably O₂/H₂S about 0.5.

The catalytic reactor is operated above the dew point of the sulfur in the system to avoid undesired condensation of sulfur in the reactor and to facilitate recovery of the sulfur by condensation of the sulfur vapor in a condenser. The dew point temperature determines the minimum usable catalyst bed temperature (to avoid condensation in the bed) and this is a function of the inlet H₂S concentration and H₂S conversion in the catalytic reactor. Dew point temperatures for different starting sulfur vapor concentrations are readily calculated using known methods. The preferred operating temperature of the catalytic bed is between about 160°C and about 200°C, more preferably between about 170°C and about 200°C, depending on the amount of H₂S in the feed stream. The direct oxidation catalyst (compositions as described above), makes a small amount of SO₂, CO₂, water vapor and unreacted H₂S exit the direct oxidation reactor and enter the sulfur condenser (417).

In the inventive process, elemental mercury reacts with sulfur to form HgS. The process is controlled so that HgS condensation occurs in the sulfur condenser. HgS is primarily expected in the condenser at 130 to 150°C. Some HgS formation is predicted at temperatures up to 180°C, which is the low temperature end of an H₂S catalyst operated from 170 to 200°C. The formation of HgS can be predicted by methods known to the art on the basis of the temperature, pressure, and reactants present in the system. The amount of sulfur thermodynamically required to form HgS is the same as the mercury concentration (less than about 1 ppm). However, in practice, sulfur should be generated sufficiently in excess of the amount of Hg present to ensure high efficiency removal.

Sulfur is condensed as a liquid and is sent to storage. The condenser is operated at a temperature low enough to collect sulfur as a liquid, but not so low that solid sulfur freezes in the condenser. The efficiency of sulfur and HgS removal may depend on the sulfur condenser design. Sulfur condenser designs are discussed in Kohl and Nielsen and Fenderson. The processed gas stream is passed downstream (outlet 419) for further processing (e.g., tail gas treatment) if required. Gas exiting the sulfur condenser may optionally be recycled (405) back through the catalytic reactor. If the H₂S content of the processed gas stream is sufficiently low, the treated gas may be flared or passed to an incinerator.

The configuration of FIG. 2 is an exemplary configuration used to increase sulfur recovery. H₂S, SO₂, or both are removed by the amine unit (502) and recycled (505) back to the direct oxidation reactor (501) where recycled H₂S and SO₂ are converted to additional sulfur. The gas exiting the sulfur condenser (507) is further cooled (air-fin cooler (510) or any other cooling means) before entering a standard amine gas absorption system (absorber 515 and regenerator 520). The amine chosen for use in the absorber depends on the composition of the gas exiting the sulfur condenser, which in turn, is a function of the composition of the natural gas being treated by direct oxidation. In general, the amine is selected to maximize removal of H₂S, SO₂, and CO₂ in the absorption step. The absorber is preferably designed so that the sweetened gas exiting at outlet 511 meets pipeline specifications.

The use and operation of amine gas absorption systems is well-known in the art. Rich amine from the gas absorber is sent to the amine regenerant unit (520). Stripped gas (enriched in H₂S, SO₂, and CO₂) from the regenerator is recycled (505) to the direct oxidation reactor (501). The recycle stream (505) from the amine unit regenerator is mixed with the incoming sour gas and heated. The direct oxidation reaction is responsible for recovering the sulfur present (believed to recover 85-95% of the sulfur present) in the natural gas. The direct oxidation of H₂S (Equation 1) and the Claus reaction of H₂S with SO₂ (Equation 2) function for generation of additional sulfur. In a preferred process configuration in combination with an amine unit, the catalysts and reaction conditions in the catalytic reactor are adjusted to minimize SO₂ generation.

H₂S Oxidation and Hg Removal Combined with a Liquid Phase Claus Process

FIG. 3 schematically illustrates a sulfur recovery configuration in which a direct oxidation reactor of this invention (e.g., the reactor of FIG. 1) is positioned upstream of a liquid.
phase Claus process (aqueous or non-aqueous liquid phase), as exemplified by the non-aqueous liquid phase Crysta-
sluf™ process. Again the process is illustrated for treatment of natural gas or synthesis gas, but can also be applied to
refinery fuel gas and for hydrogen recycle gas streams in a
refinery. Sour gas enters the oxidation and Hg removal
process (601) at inlet 603. The inlet line is provided with
an optional bypass (665) where a selected portion of the sour
gas can be diverted past the oxidation reactor (flow
controllers and metering valves not shown). The bypass line rejoins
the gas stream exiting (607) the catalytic reactor of the
oxidation process. The gas stream exiting the oxidation
process along with any sour gas passed through the bypass
line is introduced into the liquid phase Claus system (609).
For example, the gas stream would be introduced into the
absorber of a Crystasulf™ unit. Sweetened gas exits the
system (611) or may be passed to another process system.

The gas stream can be split using the bypass to adjust the
H₂S to SO₂ ratio of the gas that enters the liquid phase Claus
unit. Some of the flow passes through the catalytic reactor and
preferably all of its H₂S is converted into SO₂. The balance of the stream is then blended with the gas exiting the
reactor and this mixture is then sent to the liquid phase Claus
(e.g., Crystasulf™) unit. By controlling the splitting ratio to
the catalytic reactor, the blended stream will contain the
correct proportions of H₂S and SO₂ for removal of the
remaining sulfur using the liquid phase Claus process.

The liquid phase Claus process runs the Claus reaction in
liquid phase (Equation 2). In a preferred embodiment, the direct
oxidation catalytic process is used to oxidize approximately
5% of the H₂S in the natural gas stream into SO₂ so that the
proper H₂S to SO₂ ratio (2:1) is present in the natural gas
when it enters the liquid phase Claus process. The exact
amount of gas sent to the catalytic reactor depends on how
much elemental sulfur is recovered directly in the H₂S
oxidation step. The more sulfur that is recovered from the
catalytic step, the greater the proportion of gas flow that
must be sent to the reactor. However, the more sulfur that is
recovered from the catalytic reactor, the lower the sulfur
load for the liquid phase Claus process. Thus, there is a tending
off in operation of the combined configuration between the
capital and operating costs between the feed and reactor and
the absorber. The optimum operating conditions depend on
the activity of the solid catalyst and its selectivities for SO₂
and elemental sulfur.

Because methane and light hydrocarbons are inert over
the catalysts of this invention, the H₂S oxidation can be
carried out in-situ in a natural gas stream; no upstream H₂S
processing is needed. In-situ oxidation can generate a pre-
ferred H₂S:SO₂ ratio of 2:1 within the natural gas stream for
feeding to the liquid phase Claus.

In an exemplary embodiment, a selected amount of air
(e.g., 3000 ppm for 2000 ppm of H₂S) is mixed with the
natural gas and the stream is passed through a fixed bed
reactor containing the catalyst. The stream exiting the reac-
tor contains a H₂S:SO₂ ratio of about 2. The gas exiting the
reactor contains the residual natural gas components plus
H₂S and SO₂ in the proper ratio for processing in the liquid
phase Claus reaction where H₂S reacts with the SO₂ to
produce solid sulfur and water.

The configuration in which direct oxidation is combined
with a liquid Claus sulfur removal process, particularly the
non-aqueous liquid phase Claus process (e.g., Crystasulf™
process, can be employed in the treatment of high-pressure
as well as low pressure gas streams for H₂S removal.

H₂S Oxidation and Hg Removal Combined with Liquid
Redox Sulfur Removal

FIG. 4 schematically illustrates a sulfur removal/recovery
configuration in which a direct oxidation reactor of this
invention (e.g., the reactor of FIG. 1) is positioned upstream
of a liquid redox sulfur removal process, as exemplified by the
LO-CAT process. Again the process is illustrated for
treatment of natural gas or synthesis gas, but may be applied to
refinery fuel gas and hydrogen recycle streams in refineries.
The inventive catalyst and process for sulfur removal
can be used upstream of the LO-CAT process to remove
the size of the LO-CAT unit to reduce both capital costs and
operating costs for sulfur recovery. Sour gas enters the
oxidation process (601) at inlet 703. Elemental sulfur gen-
erated by direct oxidation is removed by condensation and
gas exiting the oxidation processes (707) which contains
unconverted H₂S is passed to the liquid redox process (709).
For example, the gas stream exiting the oxidation process
would be introduced into the LO-CAT absorber. Sweetened
air exits the system (711) or may be passed to another
processing system.

By using sub-stoichiometric air and operating at a tem-
perature just above the sulfur dew point, the process con-
verts a portion of the H₂S into elemental sulfur, leaving the
remainer of the H₂S unconverted. Little or no SO₂ is
formed. The product gas exiting the inventive catalytic
reactor is then processed in the liquid redox unit. By first
removing the bulk of the sulfur with the inventive catalytic
process as elemental sulfur, the size of the liquid redox unit,
for example, the LO-CAT unit, can be decreased and the chemical
and operating costs of the unit will be lower compared to a
unit designed to process all of the original H₂S in the feed
stream. The direct oxidation reaction of this invention can in
general be combined with any liquid redox process, includ-
ing the LO-CAT process, the LO-CAT II process and the
Sulferox™ process.

H₂S Oxidation and Hg Removal Combined with Biological
Sulfur Removal

FIG. 5 schematically illustrates an exemplary process
configuration combining the direct oxidation and Hg
removal reaction of this invention with a biological process
for conversion of H₂S and/or SO₂ to sulfur. The process is
illustrated for treatment of natural gas or syngas, but can be
applied to other gas streams containing sulfur-containing
components. In this configuration, sour gas enters (through
inlet 803) the oxidation and Hg removal process (601) and
sulfur and mercury generated thereina is removed by con-
densation. Gas exiting the reactor (807) which may contain
unreacted H₂S, is introduced into the biological sulfur
removal process (809) (illustrated by the Shell-Paquie pro-
cess). As illustrated the oxidation reaction is operated to
maximize partial oxidation to sulfur for removal. In the
biological process, H₂S is converted in a first step to sulfide,
e.g. in a caustic reactor, and the sulfide is converted to
selected microorganisms (e.g., sulfur bacteria) to sulfur.
Cleaned or sweetened gas exits the biological process (811)
or may be passed to another processing system.

When undesired levels of SO₂ (either SO₂ originally
present in the gas stream or SO₂ generated in the oxidation
reactor (601) are present), a different biological process can
be employed in which any SO₂ present in the gas stream is
converted to in a first step to sulfite or sulfate (using for
example a sodium bisulfate solution to absorb SO₂).
Absorbed sulfite is reduced by the anaerobic action of a
microorganism to sulfide and the sulfide generated is oxidized under aerobic conditions in the presence of a microorganism to sulfur.

**H₂S Oxidation and Hg Removal Combined With a Split Flow Claus Process**

The inventive catalytic oxidation process can be used to replace the furnace in a split flow Claus plant for processing low concentrations of H₂S. The split flow Claus process is typically used for gases containing low concentrations of H₂S and is especially attractive for H₂S concentrations below 12% (Aleoca, 1997). FIG. 6 schematically illustrates a sulfur removal/recovery configuration in which a direct oxidizer is used in place of the absorber reactor (e.g., the reactor of FIG. 4) is positioned upstream of a liquid Claus unit. Sour gas from a source containing a low concentration of H₂S (e.g., 40% or less) is split (904 and 903). A portion of the feed gas stream (904) is directed into the Claus unit (909) and a portion (903) is introduced into the oxidation and Hg removal process (604). By controlling the amount of air (905) to the catalytic reactor (611) and operating at moderate temperatures (ca. 200°C), H₂S in the split stream (903) can be converted into SO₂ and elemental sulfur. Gas exiting the oxidation process (907) containing SO₂ is passed to the Claus unit and sulfur generated in the oxidation process is condensed. A third or more of the feed gas flow can be sent through the direct oxidation process. Diversion of feed gas flow decreases the total sulfur load on the Claus converters. After processing through the Claus process, elemental sulfur is recovered and tail gas (911) exits the system. Depending upon the residual levels of H₂S in the tail gas, it may be recycled through the oxidation process or passed to a second catalytic reactor for additional sulfur generation.

Feed gases with H₂S contents below about 12% can be processed without having to add fuel because the H₂S oxidation into SO₂ is catalytic and proceeds at temperatures below 500°C.

**H₂S Oxidation and Hg Removal Combined with the SCOT (Shell Claus Offgas Treatment) Process**

FIG. 7 schematically illustrates a sulfur removal/recycle configuration in which a direct oxidation and Hg removal reactor of this invention (e.g., the reactor of FIG. 4) is positioned upstream of tail gas clean-up unit, such as a SCOT unit. The process is illustrated for treatment of natural gas or synthesis gas. A SCOT process, as is known in the art, has two elements: a hydrogenation/hydrosulfurization unit, followed by a water quench and an amine gas treatment unit. Tail gas from a Claus unit is introduced into the hydrogenation/hydrosulfurization unit, heated to 250–300°C and reacted with a reducing gas (e.g., hydrogen or a mixture of hydrogen and CO) employing a cobalt molybdate catalyst. SO₂, S, COS, CS₂, and other sulfur species in the tail gas are reduced to H₂S. The temperature of the processed gas stream is lowered (water-quench to 180°C and H₂S is selectively absorbed in an amine unit (using an alkanolamine solution, for example)). H₂S is stripped from the solution and recycled back to the hydrogenation/hydrosulfurization unit.

FIG. 7 illustrates sour gas introduced (1003) into the oxidation and H₂S removal process (601). Any unconverted H₂S and SO₂ generated in the oxidation process (1007) are passed into the SCOT process (1009) and residual H₂S and SO₂ generated during hydrogenation/hydrosulfurization is recycled back (1005) to the oxidation process. Sweetened gas exits (1011) or is passed to another process system.

In the preferred mode of operation for this scheme, the reactor conditions are adjusted to obtain the highest sulfur yield. Since the SCOT process converts all sulfur compounds to H₂S for recycle, generating some SO₂ in the direct oxidation reactor does not detrimentally affect the process.

Another scheme used to clean up natural gas, syngas, or refinery fuel gas/hydrogen recycle streams is the combination of direct oxidation with the use of a scavenger system behind it. For small sulfur loads, this combination may be more economical than direct oxidation in combination with liquid sulfur recovery systems discussed above. The scavenger system has low capital costs and the disposable scavengers (e.g., iron-based scavengers) provide excellent economics when gas streams contain small quantities of H₂S.

Alternatively the H₂S oxidation process of this invention can be used alone or simply in combination with a hydrogenation/hydrosulfurization unit to treat Claus tail gas streams.

The processes of this invention are applicable to high-pressure natural gas streams and to the removal of H₂S and Hg from a hydrogen recycle stream or refinery hydrotreater (see Ruxter, 2002). The processes are also applicable to removal of H₂S and Hg from low pressure gas streams, e.g., for treatment of refinery fuel gas, gasification streams, synthesis gas and gas streams from CO₂ floods. The catalysts and catalytic methods of this invention for oxidation of H₂S have been found to selectively oxidize H₂S in the presence of CO and hydrogen without significant oxidation of CO or hydrogen. As a consequence of this finding, the methods herein can be used directly to treat syngas to remove H₂S and Hg.

More specifically, in the inventive process for desulfurization and Hg removal of gasification products containing CO and hydrogen, a selected amount of oxygen (typically added as air) is added to the gasification product stream and the mixture is contacted with the mixed metal oxide catalyst at temperatures between about 100°C and about 500°C preferably between about 160°C to about 250°C, more preferably between about 170°C to about 200°C, where the H₂S is partially oxidized into elemental sulfur and water or fully oxidized to give SO₂. The relative amounts of H₂S and SO₂ can be selected by adjustment of the O₂ to H₂S ratio in the feed gas for a given catalyst and the temperature. Further, the composition of the catalyst can be chosen and in combination with adjustment of the O₂ to H₂S ratio in the feed gas the relative amounts of H₂S and SO₂ generated by the direct oxidation process can be controlled.

The preferred space velocity of the reaction is between about 100 and about 10,000  m³ of gas/m³ of catalyst/hour, and the processes can be operated at ambient pressure and at higher pressures up to about 1,000 psi.

In the inventive process, the H₂S is oxidized to elemental sulfur and water (and some SO₂) without oxidizing either the CO or H₂S substantially. Because the catalyst will oxidize H₂S but not oxidize CO or H₂S, syngas containing H₂S can be directly treated. A catalyst that oxidizes CO or H₂S would be unsuitable in this application.

For H₂S concentrations below about 5%, the oxidation of H₂S into sulfur and water can be done using an adiabatic fixed bed reactor. For concentrations higher than about 5% by volume, internal cooling or multiple stage reactors can be used to reduce the exothermic heat of reaction of H₂S oxidation.

By adjusting the amount of air (O₂) added to the gas stream, the catalyst temperature and the catalyst composition, the ratio of elemental sulfur to SO₂ exiting the catalytic reactor can be adjusted to a selected value. This was demonstrated by the tests with the Co-promoted catalyst and O₂/H₂S=1.0 and O₂/H₂S=0.7. This ability to selectively
adjust the relative yields of elemental sulfur and SO₂ provides a very flexible oxidation process that can be optimized for use as an upstream technology for various sulfur recovery processes, including liquid-redox processes, conventional Claus processes and liquid phase Claus processes.

The following examples further illustrate the invention, but are in no way intended to unduly limit the invention.

**EXAMPLES**

**Example 1**

**Equilibrium Calculations**

A typical composition of syngas is shown in Table 3. For high sulfur coal, the H₂S concentration was assumed to be 10,000 ppm. For low sulfur coal, the H₂S concentration was assumed to be 100 ppm. This composition was assumed for all the equilibrium and economic analyses in this section. The pressure was assumed to be 30 atmospheres. The syngas enters the direct oxidation and mercury removal reactor. The hydrogen sulfide is oxidized to sulfur and water (>98% conversion of H₂S to S). The molar composition of the gas stream at the direct oxidation reactor outlet is shown in Table 4. The sulfur that is formed in the reactor is then cooled to between 120-140°C in a sulfur condenser, where the sulfur vapors are condensed into molten sulfur. The molten sulfur drains out of the sulfur condenser and is collected for disposal.

**Example 2**

**Economics**

An economic analysis of the Hg removal in the gasified stream has been undertaken. For high sulfur coal, 10,000 ppm H₂S was used as the basis concentration in the gas. For low sulfur coal, 800 ppm was used H₂S in the gas. For the high sulfur coal, assuming that all the sulfur is land filled (at an expense of $25/ton) and adding an opportunity cost of $35/ton (for not being able to use the sulfur), we arrive at a cost of $479/£f of mercury disposed. For the low sulfur coal, with the same assumptions, we arrive at a cost of $384/£f of mercury.

In the second case, we assumed that, instead of land filling the sulfur, we will be distilling the sulfur so that, the mercury and sulfur are separated. Using this method, we have assumed that 90% of the sulfur will be free of Hg and will be available for sale. The remaining 10% of the sulfur which will be combined with the mercury will need to be land filled. In addition, we have calculated a capital cost of $20/ton sulfur for the still. Heating costs for distillation have also been calculated and added to the overall cost of mercury removal. Using this approach, we arrive at $1835/£f Hg. This is by far the best option for processing high sulfur coal.

**Example 3**

**Sulfur Dew Point**

To avoid bed fouling or equipment plugging, it is preferred to operate a catalytic reactor of this invention in a pressure and temperature regime where any elemental sulfur formed in the reaction will remain in the vapor phase. The experiments reported show that for the best catalysts, the preferred operating temperature was 250°C. The dew point pressure for elemental sulfur at 250°C determines the maximum concentration of sulfur vapor that can be present over the catalyst. This is linked to the maximum allowable H₂S concentration via the selectivities to SO₂ and sulfur. Higher selectivities to SO₂ permit the processing gases with higher H₂S concentrations.

An example of how the maximum allowable H₂S concentration is calculated is discussed below. Sulfur vapor-liquid-equilibrium (VLE) calculations can be readily performed for different temperatures and concentrations of sulfur vapor. At T = 250°C, for 2000 ppm of elemental sulfur vapor condensation starts at a pressure of 72 bar (1044 psi). For the TDA82 (5% Fe₃O₄, 0.5% MoO₃, 5% Nb₂O₅, 5% TiO₂) catalyst the best conditions observed were O₂/H₂S = 1.5 and T = 250°C. Under these conditions the selectivity for sulfur was 30% and the selectivity for SO₂ was 70%. Assuming that the pressure affects the sulfur dew point more than the kinetics of the catalytic reaction, then the maximum concentration of H₂S that could be present in the reactor feed would be 6666 ppm for these values of S and SO₂ catalyst selectivity. These pressures (72 bar) and concentrations (6900 ppm) are somewhat approximate because the calculations do not include corrections for non-ideal gas behavior; however, the calculations do indicate that natural gas streams containing a fairly wide range of H₂S concentrations at pressures of interest (i.e., pressure up to 1000 psi) can be processed in using catalysts of this invention.

Those of ordinary skill in the art will appreciate that methods and known in the art and can be applied or readily adapted to the practice of this invention without resort to undue experimentation. For example, methods for synthesis of mixed metal oxides other than those specifically exemplified are known in the art and can be applied to the preparation of catalysts. All art-known equivalents of materials, methods specifically exemplified herein are intended to be encompassed by this invention. All references cited herein are incorporated by reference.
REFERENCES

We claim:

1. A method for simultaneous removal of hydrogen sulfide or other sulfur-containing compounds and mercury from a gas stream which comprises the steps of:

a. contacting the gas stream containing hydrogen sulfide or other sulfur-containing compounds and mercury with a mixed metal oxide catalyst at a temperature equal to or less than about 400°C in the presence of oxygen such that a substantial amount of the hydrogen sulfide or other sulfur-containing compounds present in the gas stream is oxidized to sulfur; and

b. condensing the sulfur out of the gas stream whereby mercaric sulfide formed into the sulfur generated with mercury in the gas stream is also condensed with the sulfur, wherein the mixed metal oxide catalyst comprises a low oxidation activity metal oxide selected from the group consisting of titania, silica, zirconia, alumina and mixtures thereof and one or more higher oxidation activity metal oxides.

2. The method of claim 1 wherein the low oxidation activity metal oxide is titania, silica, alumina or mixtures thereof.

3. The method of claim 1 wherein the gas stream comprises hydrocarbons, oxygenated hydrocarbons, sulfur-containing hydrocarbons, aromatic hydrocarbons, aliphatic hydrocarbons, hydrogen, carbon monoxide or mixtures thereof.

4. The method of claim 1 wherein the gas stream comprises hydrogen, carbon monoxide or mixtures thereof.

5. The method of claim 1 wherein the gas stream comprises hydrocarbons.

6. The method of claim 1 wherein the gas stream comprises methane.

7. The method of claim 1 wherein the gas stream is a natural gas stream or a synthesis gas stream.

8. The method of claim 1 wherein the gas stream comprises aromatic hydrocarbons.

9. The method of claim 1 wherein the temperature at which the catalyst is contacted with the gas stream in the presence of oxygen is less than 400°C.

10. The method of claim 9 wherein the temperature is between about 150° C and about 250° C.

11. The method of claim 9 wherein the temperature is between about 170° C and about 200° C.

12. The method of claim 1 wherein 85% by volume or more of the hydrogen sulfide or other sulfur-containing compounds in the gas stream is converted to sulfur, or a mixture of sulfur and sulfur dioxide.

13. The method of claim 1 wherein the hydrogen sulfide in the gas stream is converted substantially to sulfur.

14. The method of claim 1 wherein the low oxidation activity metal oxide is titania or a mixture of titania with silica.

15. The method of claim 1 wherein the low oxidation activity metal oxide is titania.

16. The method of claim 1 wherein the low oxidation activity metal oxide is an alumina.
17. The method of claim 16 wherein the alumina is alpha alumina or gamma alumina.

18. The method of claim 1 wherein the low oxidation activity metal oxide is selected from the group consisting of titania, silica, alumina and mixtures thereof and the higher oxidation activity metal oxide is an oxide of a metal selected from the group consisting of V, Cr, Mn, Fe, Co, Ni, Cu, Nb, Mo, Te, Ru, Rh, Ir, Ta, W, Au, La, Ce, Pr, Nd, Pm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu and mixtures thereof.

19. The method of claim 18 wherein the higher oxidation activity metal oxide is an oxide of a metal selected from the group consisting of Fe, Co, Mn, Cr, Cu, Mo, Nb, and mixtures thereof.

20. The method of claim 18 wherein the higher oxidation activity metal oxide is a metal oxide of a transition metal or a mixture of transition oxides of lanthanide metals.

21. The method of claim 1 wherein the mixed metal oxide catalyst comprises one or more metal oxides of lanthanide metals.

22. The method of claim 1 wherein the mixed metal oxide catalyst comprises titania, silica, alumina or mixtures thereof in combination with one or more metal oxides of a metal selected from the group consisting of Fe, Co, Mn, Cr, Cu, Mo, Nb and mixtures thereof.

23. The method of claim 1 wherein the mixed metal oxide catalyst comprises titania, silica, alumina or mixtures thereof in combination with two or more metal oxides of a metal selected from the group consisting of Fe, Co, Mn, Cr, Cu, Mo and Nb.

24. The method of claim 1 wherein the mixed metal oxide catalyst comprises titania, silica, alumina, or mixtures thereof in combination with three or more metal oxides of a metal selected from the group consisting of Fe, Co, Mn, Cr, Cu, Mo and Nb.

25. The method of claim 1 wherein the mixed metal oxide catalyst comprises titania, silica, alumina or mixtures thereof in combination with a metal oxide of Mo, Nb or both and in combination with a metal oxide of a metal selected from the group consisting of Fe, Co, Mn, Cr, and Cu.

26. The method of claim 1 wherein the mixed metal oxide catalyst comprises titania, an oxide of Mo, an oxide of Nb and an oxide of one or more metals selected from the group consisting of Fe, Co, Cr, Mn and Cu.

27. The method of claim 1 wherein the metal oxide catalyst comprises titania, an oxide of Mo, an oxide of Nb, and an oxide of Cu or Fe.

28. The method of claim 1 wherein titania or a combination of titania and silica is present at a level of 75% by weight or more in the catalyst.

29. The method of claim 28 wherein titania or a combination of titania and silica is present at a level of 75% by weight or more in the catalyst.

30. The method of claim 28 wherein the metal oxide catalyst contains about 0.1% to about 10% by weight of each of one, two, three or four metal oxides wherein the metal oxide is a metal oxide of a metal is selected from the group consisting of Fe, Co, Mn, Cr, Cu, Mo and Nb.

31. The method of claim 1 wherein the metal oxide catalyst comprises from 0.1% to about 10% by weight of an oxide of Mo, an oxide of Nb or both and contains from about 1% to about 10% by weight of an oxide of Mo, an oxide of Cu or both.

32. The method of claim 1 wherein the catalyst comprises about 1% to about 10% by weight copper oxide, about 1% to about 10% by weight niobium oxide, and about 0.1% to about 1% by weight molybdenum oxide with the remainder being titania or a mixture of titania and silica.
49. The method of claim 47 which further comprises the step, after condensation of sulfur and mercuric sulfide, of treating the gas stream with a biological sulfur removal process for removal of remaining undesired H₂S.

50. The method of claim 47 which further comprises the step, after condensation of sulfur and mercuric sulfide, of treating the gas stream with a scavenger process for removal of remaining H₂S.

51. The process of claim 47 which further comprises the step, after condensation of sulfur and mercuric sulfide, of treating the gas stream with an amine separation unit to separate H₂S, SO₂ or both from the product gas to generate a feed gas stream containing H₂S, SO₂ or both which is thereafter returned to step a.

52. The process of claim 47 wherein the gas stream is a natural gas stream or a synthesis gas stream containing H₂S and mercury.

53. The process of claim 1 wherein the gas stream contains from about 1 ppb to about 1 ppm mercury.
